- 3 Universe evolution with and without phase transition
- 4 The two-measures theory – including the inflaton
- 5 Conclusions

# The current state of cosmology

What we know :

- The Universe is isotropic and homogeneous
- The Universe is expanding in an accelerated rate
- The Universe is flat (within error of  $\sim 0.4\%$  by WMAP)
- The age of the Universe is  $13.798 \pm 0.037$  bln. years
- The Universe contains  $4.82 \pm 0.05\%$  ordinary matter,  $25.8 \pm 0.4\%$  dark matter and  $69 \pm 1\%$  dark energy.

Data from Planck, SNe Ia, the HST key project, the Sloan Digital Sky Survey, WMAP, COBE, large-scale galaxy

To extend  $\Lambda$ -CDM, we need theory with inflation and with DE/DM!

# The history of the Universe in numbers

- Inflation:  $10^{-36} \text{ s} - 10^{-32} \text{ s}$ ,  $a(t) \sim e^t$
- Radiation Era (Photon Epoch): until  $\sim 50\,000$  Years A.B.B.,  $a(t) \sim t^{\frac{1}{2}}$
- Matter Era:  $\sim 50\,000$  years and 9.8 billion ( $a(t) = 0.00025$ ,  $z = 3600$ ),  $a(t) \sim t^{\frac{2}{3}}$  ( $z_{\text{CMB}} = 1100$ )
- Current  $\Lambda$ -dominated epoch (Dark Energy Era):  $a(t) > 0.7$ ,  $z_{\Lambda} \sim 0.33$ ,  $a(t) \sim e^t$

$$\Lambda\text{-CDM: } H^2 = \frac{\ddot{a}(t)^2}{a(t)^2}, H(z) = H_0(\Omega_M(1+z)^3 + \Omega_{\text{Rad}}(1+z)^4 + \Omega_k(1+z)^2 + \Omega_{\Lambda})$$

where  $\Omega_X = \frac{\rho_X(t=t_0)}{\rho_c}$  – present day density parameter,  $a(t) = \frac{1}{1+z}$

**Planck 2015:**  $H_0 = 67.31 \pm 0.96 \text{ km/s/Mpc}$ ,  $\Omega_{\Lambda} = 0.685 \pm 0.013$ ,  $\Omega_m = 0.315 \pm 0.013$

# The darkon model in FLRW metric, Mod. Phys. Lett. A, 32, 1 (2017)

If we apply the two-measures darkon model in the  $f(R)$  gravity (Guendelman, Nissimov and Pacheva ([1],[2])),

$$S_{\text{darkon}} = \int d^4x \sqrt{-g} (R(g, \Gamma) - \alpha R^2(g, \Gamma)) + \int d^4x (\sqrt{-g} + \Phi(C)) L(u, X)$$

with  $\Phi(C) = \frac{1}{3} \epsilon^{\mu\nu\kappa\lambda} \partial_\mu C_{\nu\kappa\lambda}$ ,  $L(u, X) = -\frac{1}{2} g^{\mu\nu} \partial_\mu \phi \partial_\nu \phi - V(\phi)$

The Friedman–Lemaître–Robertson–Walker metric with  $k = 0$  is:

$$ds^2 = -dt^2 + a(t) [dr^2 + r^2 (d\theta^2 + \sin^2 \theta d\varphi^2)] .$$

From the Friedman equations ( $G_{00} = T_{00}$ ), the energy density is:

$$\rho = \frac{1}{8\alpha} \dot{u}^2 + \frac{3}{4} \frac{p_u}{a(t)^3} \dot{u} - \frac{1}{4\alpha} \quad (1)$$

where for the constant  $p_u$  we have from the equation of motions:

$$a(t)^3 \left[ -\frac{1}{2\alpha} \dot{u} + \left( \frac{1}{4\alpha} - 2M \right) \dot{u}^3 \right] = p_u \quad (= \text{const}) \quad (2)$$

# The miracles of a simple cubic equation

We rewrite the last cubic equation for  $\dot{u}$  Eq. (2), as

$$y^3 + 3ay + 2b = 0 \text{ with } a = -\frac{2}{3-24\alpha M} \text{ and } b = -\frac{2\alpha p_u}{a(t)^3(1-8\alpha M)}.$$

The solutions are:

$$y_1 = -\frac{a}{(-b + \sqrt{a^3 + b^2})^{1/3}} + (-b + \sqrt{a^3 + b^2})^{1/3}$$

$$y_2 = \frac{a}{(b - \sqrt{a^3 + b^2})^{1/3}} - (b - \sqrt{a^3 + b^2})^{1/3}$$

$$y_3 = \frac{1-i\sqrt{3}}{2} \frac{a}{(-b + \sqrt{a^3 + b^2})^{1/3}} - \frac{1+i\sqrt{3}}{2} (-b + \sqrt{a^3 + b^2})^{1/3}$$

No real smooth solution exists in the  $[a, b]$  plane.

We define the following piecewise functions, **real** in the whole plane  $[a, b]$

$$y_b = \begin{cases} y_1 & \text{for } (a, b) \in \{a \geq 0\} \cup \{a < 0 \cap b < 0\} \\ y_2 & \text{for } (a, b) \in \{a < 0 \cap b > 0\} \end{cases}$$

$$y_s = \begin{cases} y_1 & \text{for } b > 0 \\ y_2 & \text{for } b < 0. \end{cases}$$

# Universe evolution with and without phase transition

After rescaling time by  $2|\alpha|/3 = 1$  and absorbing  $\alpha$  into Hubble constant ( $\bar{\rho} = 4|\alpha|\rho$ ):

Final form of the Friedman equation:

$$\left(\frac{\dot{a}(t)}{a(t)}\right)^2 = \bar{\rho} = \left(\frac{1}{2}y^2 + \frac{\mathbf{b}}{\mathbf{a}}y - 1\right) \quad (3)$$

$$\bar{\rho} \xrightarrow{a(t) \rightarrow \infty} 1 \text{ for } \mathbf{a} > 0$$

$$\bar{\rho} \xrightarrow{a(t) \rightarrow \infty} -\frac{3}{2}\mathbf{a} - 1 \text{ for } \mathbf{a} < 0 \quad (4)$$

We use as independent real solutions  $y_b$  (our basic solution) and  $y_s$  and integrate numerically Eq. 3 to find the evolution of the universe.

Graphics of the  $a(t)$  evolution for:  $\mathbf{a} = -0.5, \mathbf{b} = -\frac{0.5}{a^3}$  (blue),  $\mathbf{a} = -1, \mathbf{b} = -\frac{2}{a^3}$  (red),  $\mathbf{a} = 1, \mathbf{b} = \frac{6}{a^3}$  (green) and  $t_p = 1.5074, a_s(t_p) = 2.0825$  (purple).

# Universe evolution with phase transition

- We denote  $\bar{\rho}$  the density which corresponds to solution  $y_s$ .
- For  $t = 1$ ,  $\bar{\rho}(t_3) < 0$ , but for certain moment  $t_p$ :  $\bar{\rho}(a(t_p)) = 0$  (same asymptotic for large  $a(t)$ ).
- Therefore, for any moment after  $t_p$  we have two "states"  $\bar{\rho}$  and  $\bar{\bar{\rho}}$  of the Universe:

$$0 \leq \bar{\bar{\rho}} < \bar{\rho} \text{ for } t \geq t_p. \quad (5)$$

This opens the possibility the Universe to undergo "**phase transition**" or "**quenching**" to the lower state.

- The moment of the phase transition is crucial for the further evolution:
  - If it happens exactly at time  $t_p$  the evolution **stops** ( $\bar{\bar{\rho}} = 0$ ).
  - If the jump occurs in any later moment, then we observe **phase transition of the first kind**.

# The supernova data fit

Distance modulus  $d_m$ :

$$d_m = 5 \log_{10} \left( \frac{d}{10} \right) \quad (6)$$

where  $d$  is the distance in parsecs.

Connection between  $d_m$  and  $z$ :

$$\begin{aligned} d_m &= 5 \log_{10} \left( (1+z) \int_0^z dx \frac{a(x)}{\dot{a}(x)} \right) = \\ &\text{const} + 5 \log_{10} \left( (1+z) \int_0^z dx \frac{1}{\sqrt{\rho(x)}} \right) \end{aligned} \quad (7)$$

Where we have used  $a = \frac{1}{1+z}$ . Here,  $\rho(x)$ :

$$\rho_{CDM} \sim a(t)^{-3}, \rho_r \sim a(t)^{-4}, \rho_k \sim a(t)^{-2}, \rho_{DE} \sim \Lambda$$

From observations, we know that  $\rho_k \sim 0$ ,  $\rho_r \sim 10^{-5}$ , so we use  $\Omega_{CDM} + \Omega_{\Lambda}$  universe.

# Our best fit against Supernovae data and standard fit

**Figure:** Supernovae data against Standard model fit (dotted line),  $\mathbf{a} < -2/3$  fit (dashed line) and  $\mathbf{a} > 1$  fit (solid line).

$\chi^2 = 562$  for  $\Omega_{DE} = 0.722, \Omega_{CM} = 0.278, \Omega_K = 0, \Omega_R = 0$  :standard fit

$\chi^2 = 571$  for  $\Omega_{DE} = 0.73224, \Omega_{CM} = 0.26776, \Omega_K = 0, \Omega_R = 0$  :Misho's symplectic fit

$\chi^2 \sim 562$  for  $\mathbf{a} < -2/3$ ,

$\chi^2 \sim 578$  for  $\mathbf{a} > 1$ .

Supernova data [6] are available at [http://www.supernova.lbl.gov/Union/figuresSCPUUnion2.1\\_mu\\_vs.z.txt](http://www.supernova.lbl.gov/Union/figuresSCPUUnion2.1_mu_vs.z.txt)

The best fit of SN data using the proposed model is not unique.

We observe one parametric family of solutions which gives practically one and the same  $d_m(z)$  function.

Figure: Best fit families on the parametric plane.

# Using the so obtained $a, b$ as parameters in the evolution

Here the black line corresponds to  $a = -5.98736, b = -2.93213, t_0 = 0.72226$ .

We have an expanding Universe, but what about the inflation?

# Including inflation into the model

Following Guendelman, Nissimov and Pacheva [4, 5] (where in  $S_{darkon}$   $\alpha = 0$ )

$$S = S_{darkon} + \int d^4x \Phi_1(A)(R + L^{(1)}) + \int d^4x \Phi_2(B) \left( L^{(2)} + \frac{\Phi(H)}{\sqrt{-g}} \right)$$

where we have

$$L^{(1)} = -\frac{1}{2} g^{\mu\nu} \partial_\mu \phi \partial_\nu \phi - V(\phi), \quad V(\phi) = f_1 e^{-\alpha\phi} \quad (8)$$

$$L^{(2)} = -\frac{b}{2} e^{-\alpha\phi} g^{\mu\nu} \partial_\mu \phi \partial_\nu \phi + U(\phi), \quad U(\phi) = f_2 e^{-2\alpha\phi} \quad (9)$$

$$(10)$$

From the equations of motion we have:

$$p = -2M_0 = const, \quad \frac{\Phi_2(B)}{\sqrt{-g}} = \chi_2 = const$$

$$R + L^{(1)} = -M_1 = const, \quad L^{(2)} + \frac{\Phi(H)}{\sqrt{-g}} = -M_2 = const$$

$$U_{eff}(\phi) = \frac{(V_1(\phi) + M_1)^2}{4\chi_2(U(\phi) + M_2)} \text{ with } U_- = \frac{f_1^2}{4\chi_2 f_2}, \quad U_+ = \frac{M_1^2}{4\chi_2 M_2}$$

From the requirement that the vacuum energy density of the early Universe  $U_-$  should be much bigger than that of the late Universe  $U_+$  follows that:

$$\frac{f_1^2}{f_2} \gg \frac{M_1^2}{M_2}$$

# The effective potential

To fit the current energy density and that at Planck times:

$$|M_1| \sim M_{EW}^4, M_2 \sim M_{Pl}^4, f_1 \sim f_2 \sim 10^{-8} M_{Pl}^4$$

# The equations in FLRW

The system of equations that need to be solved in order to obtain the evolution of the Universe is the following:

$$v^3 + 3av + 2b = 0 \text{ for } \mathbf{a} = \frac{-1}{3} \frac{V(\phi) + M_1 - \frac{1}{2}\chi_2 b e^{-\alpha\phi} \dot{\phi}^2}{\chi_2(U(\phi) + M_2) - 2M_0}, \mathbf{b} = \frac{-p_u}{2a(t)^3(\chi_2(U(\phi) + M_2) - 2M_0)} \quad (11)$$

$$\dot{a}(t) = \sqrt{\frac{\rho}{6}} a(t), \rho = \frac{1}{2} \dot{\phi}^2 (1 + \frac{3}{4} \chi_2 b e^{-\alpha\phi} v^2) + \frac{v^2}{4} (V + M_1) + \frac{3p_u v}{4a(t)^3} \quad (12)$$

$$\ddot{a}(t) = -\frac{1}{12} (\rho + 3p) a(t), p = \frac{1}{2} \dot{\phi}^2 (1 + \frac{1}{4} \chi_2 b e^{-\alpha\phi} v^2) - \frac{v^2}{4} (V + M_1) + \frac{p_u v}{4a(t)^3} \quad (13)$$

$$\frac{d}{dt} \left( a(t)^3 \dot{\phi} (1 + \frac{\chi_2}{2} b e^{-\alpha\phi} v^2) \right) + a(t)^3 \left( \alpha \frac{\dot{\phi}^2}{4} \chi_2 b e^{-\alpha\phi} v^2 + \frac{1}{2} V_\phi v^2 - \chi_2 U_\phi \frac{v^4}{4} \right) = 0 \quad (14)$$

Note that here Eq. (13) is optional and it offers an independent way to evaluate  $\ddot{a}(t)$ . The differential system above is of first order with respect to  $a(t)$  and of second order with respect to  $\phi(t)$ .

To evaluate it we use the implemented in Maple Fehlberg fourth-fifth order Runge-Kutta method with degree four interpolant.

# Comparison with the darkon case

**Darkon case:**

$$\mathbf{a} = -\frac{2}{3-24\alpha M} \text{ and } \mathbf{b} = -\frac{2\alpha p_u}{a(t)^3(1-8\alpha M)}.$$

$$\bar{\rho}_D = \left( \frac{1}{2}y^2 + \frac{\mathbf{b}}{\mathbf{a}}y - 1 \right)$$

**Inflaton case:**

$$\mathbf{a} = -\frac{1}{3} \frac{V(\phi) + M_1 - \frac{1}{2}\chi_2 b e^{-\alpha\phi} \dot{\phi}^2}{f_\phi}, \quad \mathbf{b} = \frac{-p_u}{2a(t)^3 f_\phi}$$

$$\rho_I = \frac{1}{2} \dot{\phi}^2 (1 + v^2 \chi_2 b e^{-\alpha\phi}) - \frac{3}{2} f_\phi \left( \mathbf{a} \frac{v^2}{2} + \mathbf{b} v \right),$$

where  $f_\phi = \chi_2(U(\phi) + M_2) - 2M_0$  and

$$\frac{d}{dt} \left( a(t)^3 \dot{\phi} \left( 1 + \frac{\chi_2}{2} b e^{-\alpha\phi} v^2 \right) \right) + a(t)^3 \left( \alpha \frac{\dot{\phi}^2}{4} \chi_2 b e^{-\alpha\phi} v^2 + \frac{1}{2} V_\phi v^2 - \chi_2 U_\phi \frac{v^4}{4} \right) = 0$$

# The evolution of the Universe in the $[a, b]$ plane

(d) Darkon case

(e) Inflaton case

Here the evolution of the Universe starts from  $b \rightarrow -\infty$  and finishes at  $b \rightarrow 0$   
 We have chosen the parameters in such a way that  $b = \frac{-p_U}{2a(t)^3(\chi_2(U+M_2)-2M_0)} < 0$ .

Or if we zoom in

(f) Darkon case

(g) Inflaton case

We see that the horizontal lines of the simpler darkon case transform into the curved lines of the inflaton case.

# Numerical solutions - 1) The potentials

(h) Case 1

(i) Case 2

(j) Case 3

Case 1:

$M_0 = -0.01, M_1 = 0.1, M_2 = 4, \alpha = .72, b_0 = 1 \times 10^{-5}, p_U = 9 \times 10^{-3}, \chi_2 = 2 \times 10^{-4}, f_1 = 2 \times 10^{-5}, f_2 = 1 \times 10^{-8}$

Case 2:

$M_0 = -0.01, M_1 = 0.1, M_2 = 4, \alpha = .7, b_0 = 1 \times 10^{-5}, p_U = .15, \chi_2 = 3.3 \times 10^{-4}, f_1 = 3 \times 10^{-5}, f_2 = 1 \times 10^{-8}$

Case 3:

$M_0 = -.1, M_1 = .667, M_2 = 0.001, \alpha = 1, b_0 = 0.05, p_U = 0.19 \times 10^{-1}, \chi_2 = .125, f_1 = .5, f_2 = 5 \times 10^{-8}$

# Numerical solutions - the evolution

(k) Case 1

(l) Case 1

Initial and boundary conditions:

- 1)  $a(0) = 10^{-12}$ ,  $\phi(0) = \phi_0$ ,  $\dot{\phi}(0) = 0$
- 2)  $a(1) = 1$
- 3)  $a''(t) = 0$  in 3 points + correct sign

## Case 2 (up) and Case 3 (bottom)

# The energy density

# The imaginary parts

# Exploring the parameters 1

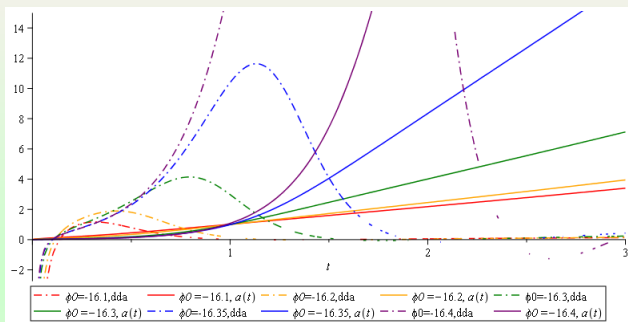

# Exploring the parameters 2

# Exploring the parameters 3

# The initial condition $\phi_0$

Which plotted on the effective potential is:

# Example of the friction stopping the inflation:

$$M_0 = -.01, M_1 = 1/10, M_2 = 4, \alpha = 0.64, b_0 = 1e-7, c_0 = 0.0067, \chi_2 = \frac{1}{5000}, f_1 = 3e-5, f_2 = 1e-8 : \phi_0 = -16.2$$

$$\dot{\phi}_{t=10} = 0.137, \phi(t=10) = -11.09$$

## Example of the friction stopping the inflation:

The evolution is not able to reach the  $U_+$  region within realistic time-frame.

# Where are we?

The main requirement of the model:

$$f_1^2 / f_2 \gg M_1^2 / M_2$$

is satisfied for all our numerical results.

Parameter	Theory	Numerics	Comment
$M_1$	$\sim M_{EW}^4 = 4.10^{-60}$	$1/15 = 6.67 \times 10^{-2}$	gauge $M_{PI} = \sqrt{2}$
$M_2$	$\sim M_{PI}^4 = 4$	4	
$f_1$	$\sim 10^{-8}$	$2 \times 10^{-5}$	$f_1^2 / f_2 = 4 \times 10^{-8}, f_1 \sim f_2$
$f_2$	$\sim 10^{-8}$	$10^{-8}$	
$M_0$	$\Lambda^{PI} \sim 10^{-122}$	$\Lambda = 1.156 \times 10^{-5}$	$2\Lambda = \frac{M_1^2}{4(\chi_2 M_2 - 2M_0)}$
$\alpha$	$10^{-20} - 0.2$	0.64	$\alpha > 0.2$ - scalar-tensor ratio $\rightarrow 0$

## Time scale considerations:

Matter domination is considered to start at  $a_{MD}(t) \sim 3 \times 10^{-4}$ , the accelerated expansion - at  $a_{AE}(t) \gtrsim 0.6$ .

Current best result  $a_{MD} = 0.2, a_{AE} = 1.2$ .

More than 37 evolutions calculated.

# Conclusions

- We integrated numerically the Friedman equations in the K-essence theory in the darkon and the inflaton case
- The dependence of the evolution of the Universe on the parameters  $[a,b]$  was examined in both cases
- It was shown that in the darkon model we can obtain both a Universe with and without phase transition
- A new data fit of the SNe data was presented
- In the case of inflaton model, the parameter space of the model was studied
- Solutions with two inflationary epochs and one matter dominated were found
- It was shown that the inflation experience friction, due to which inflation stops before reaching the  $U_+$  part of the potential

# Thank you for you attention!
